## Pterostyrax corymbosa

Высота	10 - 15 m
Ширина	10-15m
Крона	oval, half-open crown
Кора и ветви	branches gray to gray brown: bark grey-brown, grooved
Лист	obovate to oval, 6-14 cm long, glossy green
Цветы	in panicles, 3-6 cm long, flowers approx. 1 cm large, white, June
Плоды	drupe, obovate, 1.2-2.2 cm, densely hairy
Колючки/шипы	None
Ядовитость	неядовитый, обычно
Вид почвы	clayed soil, loamy soil, sandy soil, calcareous soil
Мощение	неустойчив к мощению
Зона зимостойкости	7a (-17,7 до -15,0 °C)
Устойчивость к ветру	not good
Дерево-среда обитания для животных	медонос
Форма	штамбовое дерево, многоствольное дерево

Pterostyrax corymbosus is a medium-sized tree that can grow 10-15 m tall. Its broad crown is fan-shaped to round and, because of its fairly substantial leaves, dense. The twigs are grey to grey-brown, as is the older bark, which is slightly grooved. The branches are quite brittle, so they break easily during (very) strong winds. The rather large, glossy leaves have a somewhat papery feel. The mature leaves are hairless on top and hairy on the underside. The white flowers appear in broad panicles up to 6 cm long and open in June, slightly earlier than the flowers of P. hispidus. The individual flowers are about 1 cm in size and have a pleasant fragrance. They are abundantly pollinated by bees. The fruits of P. corymbosus are about 2 cm in size and densely hairy, a marked difference from the other species of Pterostyrax. Pterostyrax corymbosus grows in any type of soil, as long as it is sufficiently moist. More acidic or calcareous soil is also well tolerated. The tree has poor tolerance to prolonged drought. Naturally, P. corymbosus grows on moist, shaded mountain slopes and along streams and rivers in southwest China and Japan.
